How muscles work

Muscle cells have the ability to contract so they shorten the whole muscle

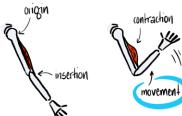

Muscle cells are ~60,000 nm in size

Muscles are connected to bones on both ends. The tissue at the end of the muscles is called tendons. The tendons are meshed into the bones.

The connection that doesn't move when the muscle contracts is called "origin". The moving side is called "insertion".

Everybody is born with a certain mixture of muscle types that can't be changed

Type I, Type II A, Type II X

"slow twitch", "medium twitch", "fast twitch"

endurance, speed, lots of speed
